Example C2

Elastic Local Buckling

$$\left(\frac{b_{el}}{t} \& \frac{h}{w} > \text{limit} \right)$$

March, 2012, 2013

Revisions:

C2-1 (example from lecture 2013-03-01)

1/3

Calculate the factored axial strength of a W360x64 of 350W steel. $F_y = 350$ MPa.

Use $L_x = 6000$ mm $L_y = 3000$ mm $K = 1.0$

W360x64:

$$A = 8140 \text{ mm}^2$$

$$r_x = 148 \text{ mm}$$

$$r_y = 48.1 \text{ mm}$$

$$b = 203 \text{ mm}$$

$$t = 13.5 \text{ mm}$$

$$d - 2t = 320 \text{ mm}$$

$$w = 7.7 \text{ mm}$$

i) local buckling

$$\text{flange: } \frac{b_{el}}{t} = \frac{203}{2 \times 13.5} = 7.52$$

$$\text{limit} = \frac{200}{\sqrt{350}} = 10.7 > 7.52 \quad \text{O.K.}$$

$$\text{web: } \frac{h}{w} = \frac{320}{7.7} = 41.6$$

$$\text{limit} = \frac{670}{\sqrt{350}} = 35.8 < 41.6 \quad \text{N.G.}$$

\therefore use § 13.3.5 to compute reduced capacity based on effective properties.

Method (a) - compute effective cross section properties.

$$\text{web: } \frac{h_e}{w} = \frac{670}{\sqrt{350}}$$

$$h_e = \frac{670}{\sqrt{350}} \times 7.7 = 275.8 \text{ mm.}$$

(if web had this h_e it would meet the slenderness limits).

$$h - h_e = 320 - 275.8 = 44.2 \text{ mm.}$$

calc. section properties of W360x64 with 44.2 mm of web removed from x-section.

C2-1 (continued)

W360x64:

$$A = 8140 \text{ mm}^2$$

reduced effective area

44.2 mm - assumed in effective

$$A_e = 8140 - 44.2 \times 7.7 = 7800 \text{ mm}^2$$

Other section properties are to be of the gross x-section (see commentary for §13.3.5)

$$\frac{K_x L_x}{r_x} = \frac{1.0 \times 6000}{148} = 40.54$$

$$\frac{K_y L_y}{r_y} = \frac{1.0 \times 3000}{48.1} = 62.37 \quad \leftarrow \text{governs}$$

$$F_e = \frac{\pi^2 \times 200000}{62.37^2} = 507.4$$

$$\lambda = \sqrt{\frac{350}{507.4}} = 0.8305$$

$$n = 1.34$$

$$C_r = \phi A_e F_y (1 - \lambda^{2n})^{-1/n}$$

$$= 0.9 \times 7800 \times 35 (1 + 0.8305^{2.68})^{-1/1.34}$$

$$C_r = 1724 \text{ kN}$$

Method (b) - compute effective $F_y = F_{ye}$

$$\frac{h}{w} = \frac{670}{\sqrt{F_{ye}}}$$

$$F_{ye} = \left(\frac{670}{h/w} \right)^2$$

$$= \left(\frac{670}{(320/7.7)} \right)^2$$

$$= 259.9 \text{ MPa}$$

$$F_e = \frac{\pi^2 \times 200000}{62.37^2} = 507.4$$

$$\lambda_e = \sqrt{\frac{259.9}{507.4}} = 0.7157$$

$$n = 1.34$$

$$C_r = 0.9 \times 8140 \times 259.9 (1 + 0.7157^{2.68})^{-1/1.34}$$

$$C_r = 1475 \text{ kN}$$

Discussion: there is a significant difference between the two methods. The designer is free to use whichever method she prefers; S16-09 does not specify that the minimum should be used.

For comparison, if the strength was not reduced by the methods of §13.3.5

$$C_r = \frac{8140}{7800} \times 1724 = 1799 \text{ kN}$$

By method (a) we have a 4% reduction in strength
